# Chapter 1

# Using the New Parser AST

The ability to simplify parsers, as well as normalising their expression arguments, makes it feasible to use the intermediate Parser AST for high-level parser transformations.

# 1.1 Removing Left-Recursion: Revisited

?? left off with a disappointing result for the left-recursion factorisation transformation, producing a mostly unreadable output in ??. This transformation can now be revisited given the improvements made to the Parser AST. The following changes can be made to improve the rule's output:

- Parser terms should be simplified via parser laws to get a more readable final output.
- Parsers should take advantage of the new Expr representation to allow for partial evaluation of higher-order functions, rather than manipulating terms as opaque quasiquotes.
- The higher-order functions flip and compose can now be represented as Expr lambda expressions, eliminating the need to patch in their definitions as previously required in ??.

Define normalise and prettify, attempt to resugar decomposed parsers back into a nicer form.

```
trait Parser {
     def normalise: Parser = this.simplify.normaliseExprs
     def isEquivalent(other: Parser) = this.normalise == other.normalise
     def prettify: Parser = this.normalise.resugar
     def resugar: Parser = this.rewrite {
          // p.map(\x -> \y -> y) <*> q == p ~> q
          case FMap(p, Abs(_{,} Abs(_{,
          // p.map(\x -> \y -> x) <*> q == p <~ q
           case FMap(p, Abs(Var(x, _), Abs(_, Var(z, _)))) <*> q if (x == z) => p <~ q
          // f.curried.map(p) <*> q == (p, q).zipped(f)
           case FMap(p1, Abs(x1, Abs(x2, body))) <*> p2 =>
                Zipped(AbsN(List(x1, x2), body), List(p1, p2))
     }.transform {
           // Scala 2 cannot resolve implicit stringLifts in some positions
          case FMap(Str(s, _), f) => FMap(Str(s, implicitSyntax = false), f)
           case Zipped(f, Str(s, _) :: ps) => Zipped(f, Str(s, implicitSyntax = false) :: ps)
}
       No .curried
trait Expr {
     def curried: Expr = this match {
           case Abs(x, f)
                                                                   => Abs(x, f.curried)
          case AbsN(x :: xs, f) \Rightarrow Abs(x, AbsN(xs, f).curried)
                                                                   => this
           case _
     }
}
```

Rocco Jiang

```
trait LiftLike extends Parser {
  def unfold() = {
    val curriedFunc = Pure(func match {
      // If the Expr is still opaque, it is treated as before
      case Translucent(term, env) => Translucent(q"($term).curried", env)
      // If statically inspectable, curry the lambda expr properly
      case _ => func.curried
    })
    parsers.foldLeft(curriedFunc)(_ <*> _).unfold
  }
}
   * no .curried * Resugaring * Optimisation: normalise leftrec part to see if it comes to empty - if so, don't
inline in the NT case
def transform(results: Option[Expr], nonLeftRec: Parser, leftRec: Parser) = {
  val result = results match {
    case None
               => Empty
    case Some(t) => Pure(t)
  }
  leftRec.normalise match {
    case Empty => Patch.empty // not left-recursive, don't rewrite
   case Pure(_) => Patch.lint(LeftRecDerivesEmptyLint) // left-recursive but unfixable
      val transformed = Postfix(nonLeftRec | results, leftRec).prettify
      Patch.replaceTree(originalTree, transformed.toString)
  }
}
```

#### The Final Result

```
lazy val example: Parsley[String] =
  chain.postfix[String](string("b"))(string("a").map(x1 => x2 => x2 + x1))
```

# 1.2 Simplify Parser

The improved Parser AST also gives a new auto-fix rule for free: automatic simplification of parsers.

Idea \* For each parser, simplify it via parser laws, and compare to its original. \* If the result is different, apply the simplified version as a patch.

The implementation of the entire rule is only 20 lines long:

```
class SimplifyParser extends SemanticRule("SimplifyParser") {
  override def fix(implicit doc: SemanticDocument): Patch = {
    getAllParserDefns.map { case ParserDefinition(_, parser, _, originalTree) =>
      val simplifiedParser = parser.prettify
    if (parser.normaliseExprs != simplifiedParser) {
      val simplifiedParserTerm = simplifiedParser.term.syntax
      Patch.replaceTree(originalTree, simplifiedParserTerm)
    } else {
      Patch.empty
```

Rocco Jiang

```
}.asPatch
}
```

 $^*$  Apply parser laws, re-using Parser and Func representations to do cool things prettify = resugar . normalise-Functions . simplify

### 1.3 Avoid Parser Redefinition

Similar in spirit to the previous rule \* Catch cases when user manually writes out a parser that is already defined in the library

?? makes it easy to write syntax-directed rewrite rules on parsers. Less annoying than working with scalameta ast directly better design patterns idk, symbolmatcher etc all in one place defined as a trait for parser

so: Looking for dumb definitions of things e.g. endBy(p, sep) implemented as many(p  $<^*$  sep); or count implemented as a foldLeft, fold fusion
